# Lecture 5. Regularisation

COMP90051 Statistical Machine Learning

Semester 2, 2018 Lecturer: Ben Rubinstein

Copyright: University of Melbourne

#### This lecture

- Regularisation
  - Irrelevant features and an ill-posed problem
  - Regulariser as prior
  - Model complexity
  - Constrained modelling
  - \* Bias-variance trade-off

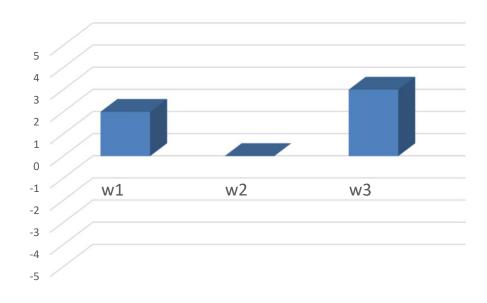

#### Regularisation

Process of introducing additional information in order to solve an ill-posed problem or to prevent overfitting

- Major technique & theme, throughout ML
- Addresses one or more of the following related problems
  - Avoids ill-conditioning
  - Introduce prior knowledge
  - Constrain modelling
- This is achieved by augmenting the objective function
- In this lecture: we cover the first two aspects. We will cover more of regularisation throughout the subject

#### Example 1: Feature importance

- Linear model on three features
  - \* X is matrix on n = 4 instances (rows)
  - \* Model:  $y = w_1x_1 + w_2x_2 + w_3x_3 + w_0$

Question: Which feature is more important?

#### **Question: Which feature is more important?**

1

2

3

I don't know

#### Example 1: Feature importance

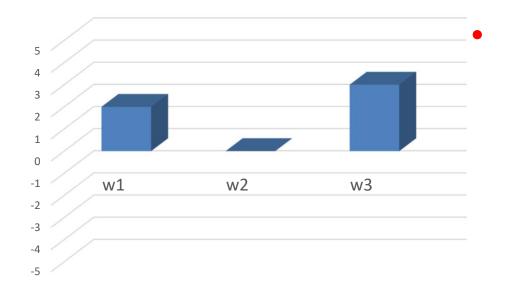

- Linear model on three features
  - \* X is matrix on n = 4 instances (rows)
  - \* Model:  $y = w_1x_1 + w_2x_2 + w_3x_3 + w_0$

#### Example 1: Irrelevant features

- Linear model on three features, first two same
  - \* X is matrix on n = 4 instances (rows)
  - \* Model:  $y = w_1x_1 + w_2x_2 + w_3x_3 + w_0$
  - \* First two columns of X identical
  - \* Feature 2 (or 1) is irrelevant

3	3	7
6	6	9
21	21	79
34	34	2

Effect of perturbations on model predictions?

- \* Add  $\Delta$  to  $w_1$
- \* Subtract  $\Delta$  from  $w_2$

#### Example 1: Irrelevant features

- Linear model on three features, first two same
  - \* X is matrix on n = 4 instances (rows)
  - \* Model:  $y = w_1x_1 + w_2x_2 + w_3x_3 + w_0$
  - \* First two columns of X identical
  - \* Feature 2 (or 1) is irrelevant

3	3	7
6	6	9
21	21	79
34	34	2

Effect of perturbations on model predictions?

- \* Add  $\Delta$  to  $w_1$
- \* Subtract  $\Delta$  from  $w_2$

#### **Question: Which feature is more important?**

1

2

3

I don't know

#### Problems with irrelevant features

- In example, suppose  $[\widehat{w}_0, \widehat{w}_1, \widehat{w}_2, \widehat{w}_3]'$  is "optimal"
- For any  $\delta$  new  $[\widehat{w}_0, \widehat{w}_1 + \delta, \widehat{w}_2 \delta, \widehat{w}_3]'$  get
  - \* Same predictions!
  - \* Same sum of squared errors!
- Problems this highlights
  - The solution is not unique
  - \* Lack of interpretability
  - Optimising to learn parameters is ill-posed problem

#### Irrelevant (co-linear) features in general

- Extreme case: features complete clones
- For linear models, more generally
  - Feature X. is irrelevant if
  - \*  $X_{.j}$  is a linear combination of other columns

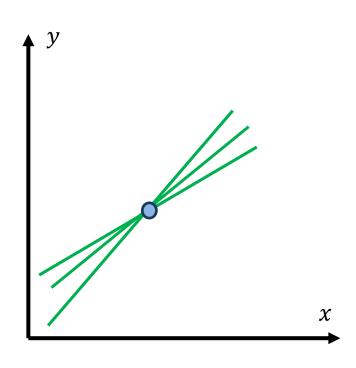

$$X_{\cdot j} = \sum_{l \neq j} \alpha_l \, X_{\cdot l}$$

... for some scalars  $\alpha_l$ 

- Even near-irrelevance can be problematic
  - \* Zero, or v small eigenvalues of X'X
- Not just a pathological extreme; easy to happen!

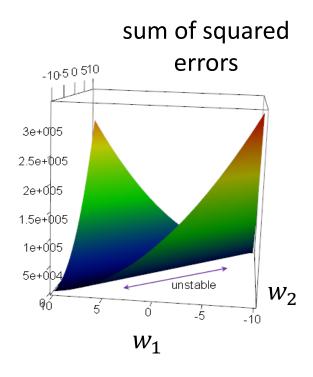

#### Example 2: Lack of data

- Model is more complex than data
- Extreme example:
  - Model has two parameters (slope and intercept)
  - \* Only one data point
- Underdetermined system

#### Ill-posed problems

- In both examples, finding the best parameters becomes an ill-posed problem
- This means that the problem solution is not defined
  - \* In our case  $w_1$  and  $w_2$  cannot be uniquely identified
- Remember the normal equations solution  $\hat{w} = (X'X)^{-1}X'y$
- With irrelevant features, X'X
  has no inverse
- The system of linear equations has more unknowns than equations

convex, but not strictly convex

#### Re-conditioning the problem

- Regularisation: introduce an additional condition into the system
- The original problem is to minimise  $\|y Xw\|_2^2$
- The regularised problem is to minimise

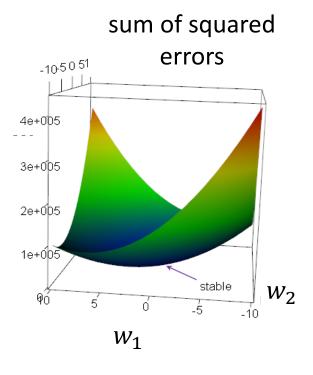

$$\|y - Xw\|_2^2 + \lambda \|w\|_2^2$$
 for  $\lambda > 0$ 

The solution is now

$$\widehat{\boldsymbol{w}} = (\boldsymbol{X}'\boldsymbol{X} + \boldsymbol{\lambda}\boldsymbol{I})^{-1}\boldsymbol{X}'\boldsymbol{y}$$

- This formation is called ridge regression
  - Turns the ridge into a peak
  - \* Adds  $\lambda$  to eigenvalues of X'X: makes invertible

strictly convex

#### Regulariser as a prior

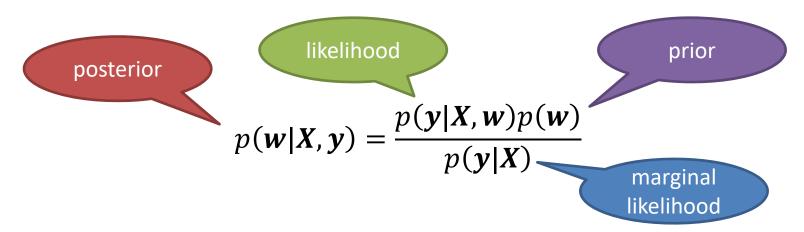

- Without regularisation, parameters found based entirely on the information contained in the training set  $\boldsymbol{X}$ 
  - Regularisation introduces additional information
- Recall our probabilistic model  $Y = x'w + \varepsilon$ 
  - \* Here Y and  $\varepsilon$  are random variables, where  $\varepsilon$  denotes noise
- Now suppose that w is also a random variable (denoted as W) with a Normal prior distribution

$$W \sim \mathcal{N}(0, \lambda^2)$$

- \* I.e. we expect small weights and that no one feature dominates
- \* Is this always appropriate? E.g. data centring and scaling
- \* We could encode much more elaborate problem knowledge

#### Computing posterior using Bayes rule

The prior is then used to compute the posterior

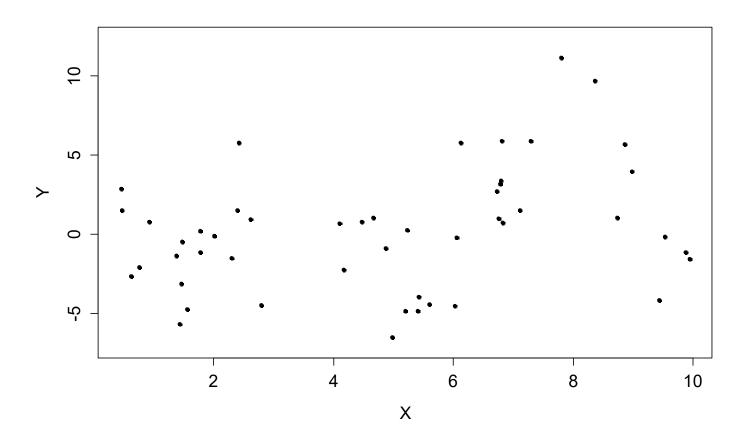

- Instead of maximum likelihood (MLE), take maximum a posteriori estimate (MAP)
- Apply log trick, so that log(posterior) = log(likelihood) + log(prior) log(marg)
- Arrive at the problem of minimising  $\|y Xw\|_2^2 + \lambda \|w\|_2^2$

this term doesn't affect optimisation

# Regularisation in Non-Linear Models

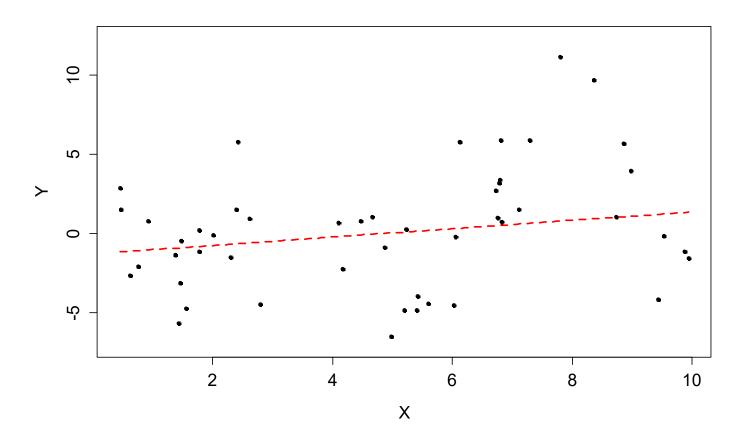

Model selection in ML

# Example regression problem

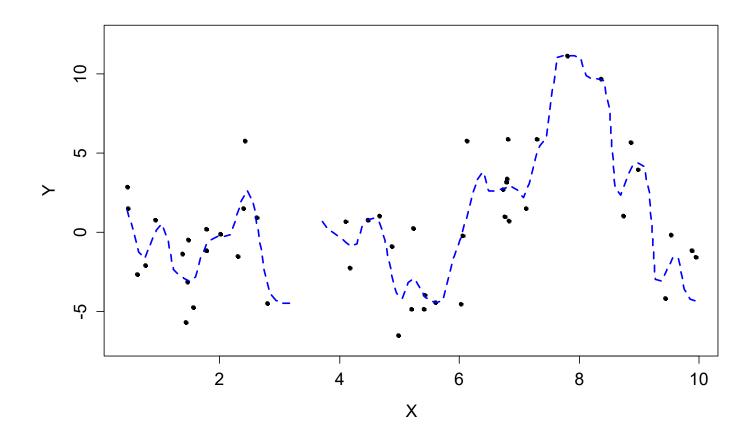

How complex a model should we use?

# Underfitting (linear regression)

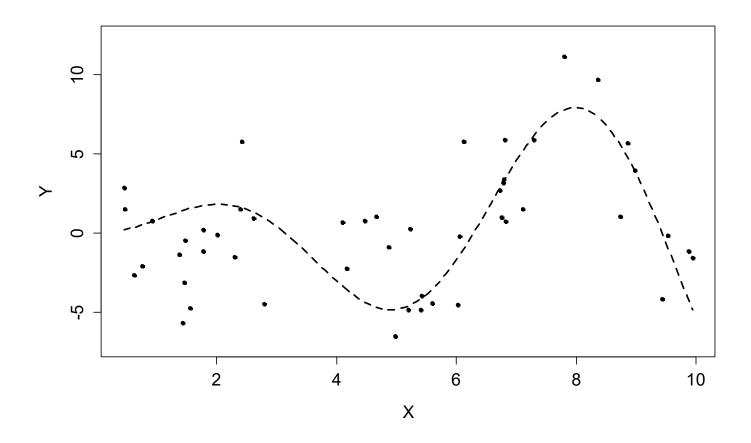

Model class  $\Theta$  can be **too simple** to possibly fit true model.

#### Overfitting (non-parametric smoothing)

Model class  $\Theta$  can be so complex it can fit true model + noise

# Actual model $(x\sin x)$

The **right model class**  $\Theta$  will sacrifice some training error, for test error.

#### How to "vary" model complexity

- Method 1: Explicit model selection
- Method 2: Regularisation
- Usually, method 1 can be viewed a special case of method 2

#### 1. Explicit model selection

- Try different classes of models. Example, try polynomial models of various degree d (linear, quadratic, cubic, ...)
- Use <u>held out validation</u> (cross validation) to select the model
- 1. Split training data into  $D_{train}$  and  $D_{validate}$  sets
- 2. For each degree d we have model  $f_d$ 
  - 1. Train  $f_d$  on  $D_{train}$
  - 2. Test  $f_d$  on  $D_{validate}$
- 3. Pick degree  $\hat{d}$  that gives the best test score
- 4. Re-train model  $f_{\hat{d}}$  using all data

## 2. Vary complexity by regularisation

Augment the problem:

$$\widehat{\boldsymbol{\theta}} \in \operatorname{argmin} \left( L(data, \boldsymbol{\theta}) + \lambda R(\boldsymbol{\theta}) \right)$$

E.g., ridge regression

$$\widehat{\boldsymbol{w}} \in \underset{\boldsymbol{w} \in W}{\operatorname{argmin}} \|\boldsymbol{y} - \boldsymbol{X}\boldsymbol{w}\|_{2}^{2} + \lambda \|\boldsymbol{w}\|_{2}^{2}$$

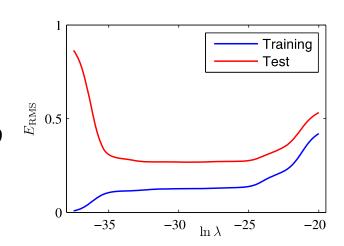

- Note that regulariser  $R(\theta)$  does not depend on data
- Use held out validation/cross validation to choose  $\lambda$

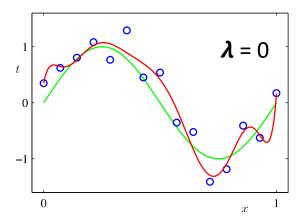

## Example: Polynomial regression

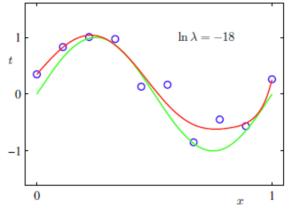

- 9<sup>th</sup>-order polynomial regression
  - \* model of form

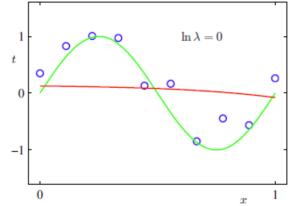

$$\hat{f} = w_0 + w_1 x + \dots + w_9 x^9$$

\* regularised with  $\lambda ||w||_2^2$  term

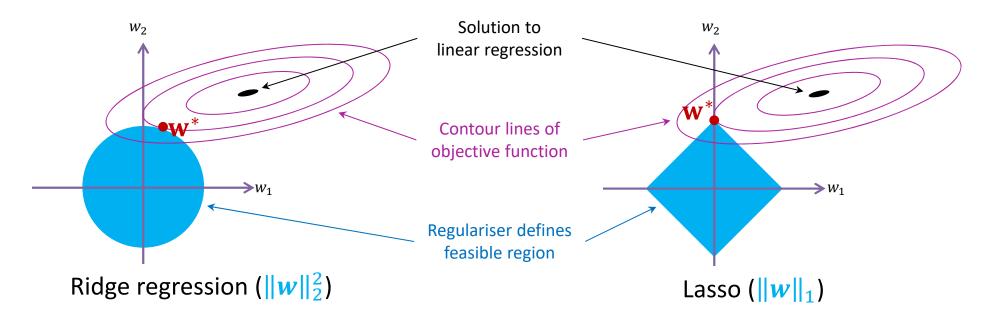

## Regulariser as a constraint

• For illustrative purposes, consider a modified problem: minimise  $||y - Xw||_2^2$  subject to  $||w||_2^2 \le \lambda$  for  $\lambda > 0$ 

- Lasso (L<sub>1</sub> regularisation) encourages solutions to sit on the axes
  - $\rightarrow$  Some of the weights are set to zero  $\rightarrow$  Solution is sparse

# Regularised linear regression

Algorithm	Minimises	Regulariser	Solution
Linear regression	$\ \boldsymbol{y} - \boldsymbol{X}\boldsymbol{w}\ _2^2$	None	$(X'X)^{-1}X'y$ (if inverse exists)
Ridge regression	$\ \boldsymbol{y} - \boldsymbol{X}\boldsymbol{w}\ _2^2 + \lambda \ \boldsymbol{w}\ _2^2$	L <sub>2</sub> norm	$(\mathbf{X}'\mathbf{X} + \lambda \mathbf{I})^{-1}\mathbf{X}'\mathbf{y}$
Lasso	$\ \mathbf{y} - \mathbf{X}\mathbf{w}\ _2^2 + \lambda \ \mathbf{w}\ _1$	L <sub>1</sub> norm	No closed-form, but solutions are sparse and suitable for high-dim data

# Bias-variance trade-off

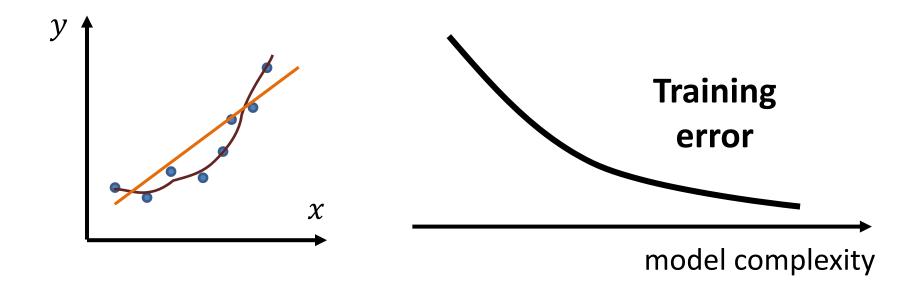

Analysis of relations between train error, test error and model complexity

#### Assessing generalisation capacity

- Supervised learning: train the model on existing data, then make predictions on <u>new data</u>
- Training the model: ERM / minimisation of training error
- Generalisation capacity is captured by risk / <u>test error</u>
- Model complexity is a major factor that influences the ability of the model to generalise
- In this section, our aim is to explore relations between training error, test error and model complexity

#### Training error and model complexity

- More complex model training error goes down
- Finite number of points  $\rightarrow$  usually can reduce training error to 0 (is it always possible?)

#### (Another) Bias-variance decomposition

Consider squared loss

$$l\left(Y,\hat{f}(\boldsymbol{x}_0)\right) = \left(Y - \hat{f}(\boldsymbol{x}_0)\right)^2$$

Lemma: Bias-variance decomposition

$$\mathbb{E}\left[l\left(Y,\hat{f}(\mathbf{x}_0)\right)\right] = \left(\mathbb{E}[Y] - \mathbb{E}[\hat{f}]\right)^2 + Var[\hat{f}] + Var[Y]$$

Risk / test error for  $x_0$  (bias)<sup>2</sup> variance irreducible error

#### Decomposition proof sketch

• Here (x) is omitted to de-clutter notation

• 
$$\mathbb{E}\left[\left(Y-\hat{f}\right)^2\right] = \mathbb{E}\left[Y^2 + \hat{f}^2 - 2Y\hat{f}\right]$$

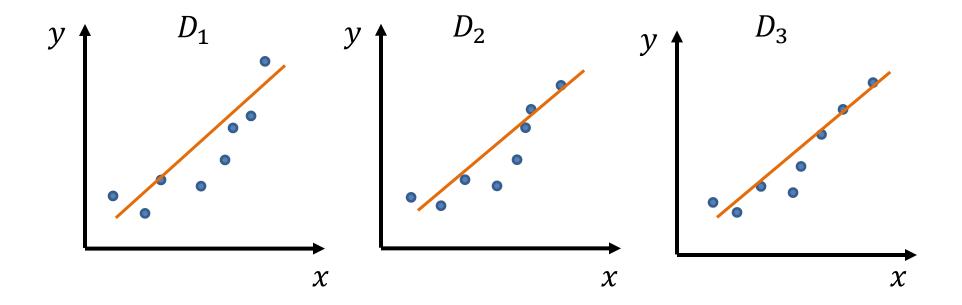

• = 
$$\mathbb{E}[Y^2] + \mathbb{E}[\hat{f}^2] - \mathbb{E}[2Y\hat{f}]$$

• = 
$$Var[Y] + \mathbb{E}[Y]^2 + Var[\hat{f}] + \mathbb{E}[\hat{f}]^2 - 2\mathbb{E}[Y]\mathbb{E}[\hat{f}]$$

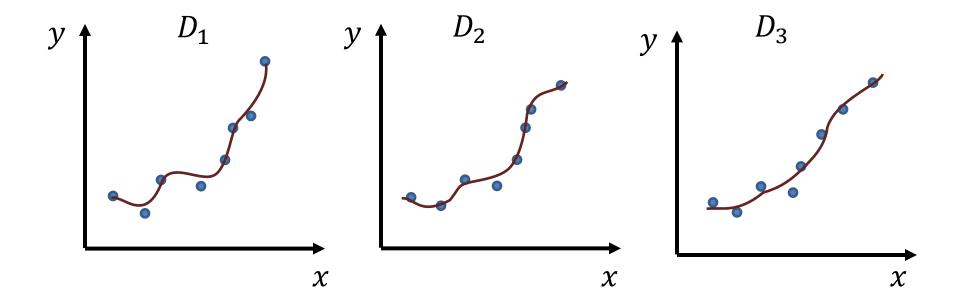

• = 
$$Var[Y] + Var[\hat{f}] + (\mathbb{E}[Y]^2 - 2\mathbb{E}[Y]\mathbb{E}[\hat{f}] + \mathbb{E}[\hat{f}]^2)$$

• = 
$$Var[Y] + Var[\hat{f}] + (\mathbb{E}[Y] - \mathbb{E}[\hat{f}])^2$$

# Training data as a random variable

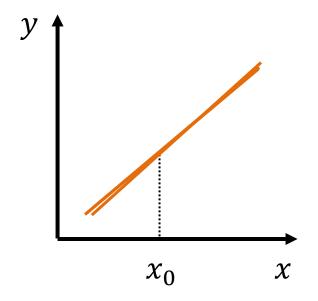

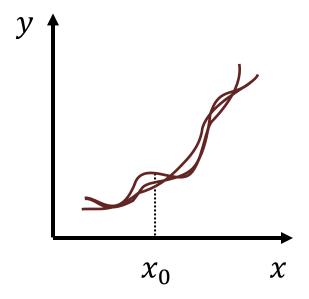

# Training data as a random variable

# Model complexity and variance

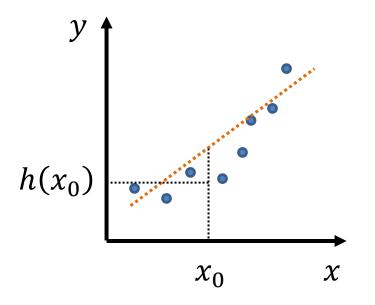

- simple model low variance
- complex model high variance

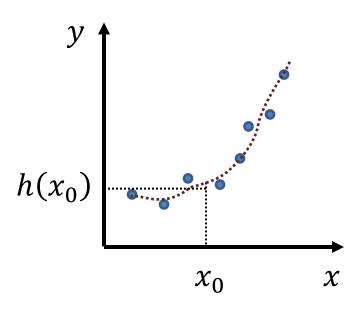

## Model complexity and bias

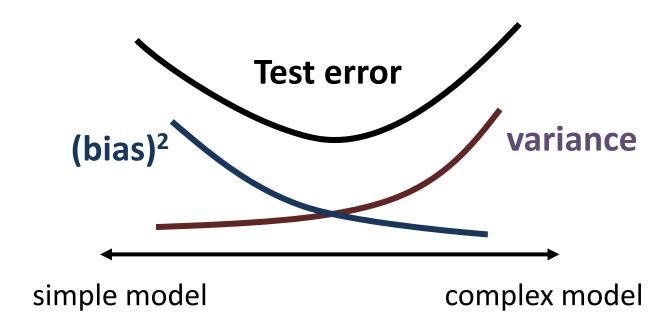

- simple model 
   high bias
- complex model → low bias

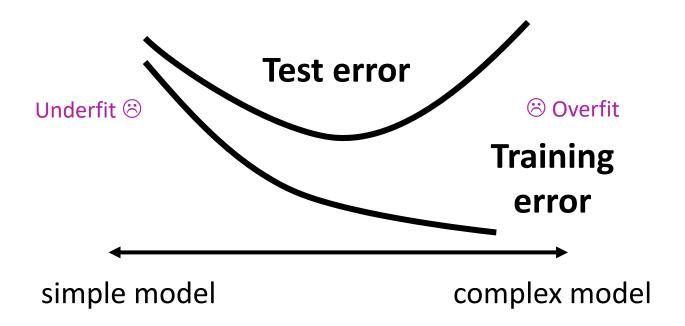

#### Bias-variance trade-off

- simple model → high bias, low variance
- complex model → low bias, high variance

## Test error and training error

#### Summary

- Regularisation
  - \* Irrelevant features, ill-posed problems
  - Model complexity
  - Constrained modelling
  - \* Bias-variance trade-off
- Workshop Week #3: fun with logistic regression
- Next lecture: Towards neural nets with perceptron
